Import Restriction, Price Shock, and Local Policy Responses: Evidence from Indonesia

This paper uses heterogeneity in the effects of rice import restriction to analyze local policy responses to rice price shocks across Indonesian villages. I exploit within village variation by interacting village agro-climatic conditions for growing rice with provincial rice price over time to obtain plausibly exogenous local price shocks. Policy responses are measured by public goods and small-scale development projects provision. I assemble a comprehensive longitudinal dataset of more than 53,000 villages and show that rice price hike led to more resources for adversely affected villages. District governments distributed more health facilities toward villages less suited for growing rice, but only for those that did not already have one. Adversely affected villages empowered themselves by launching more projects, particularly capital assistance. I identify demand-side mechanism as a key explanation: Rice price hike harmed villages less suited for growing rice in terms of aggregate income and nutrition per capita. I also find evidence suggesting the role of wealth inequality. Heterogeneity analysis suggests that the effects on health facilities (development projects) are significant only in high (low)-inequality villages. This contrasting result can partly be explained by a combination of two factors: 1) villages having more control over projects and 2) higher social capital in low-inequality villages. Finally, I find evidence suggesting good targeting performance by district governments: Public health facilities were effective in mitigating adverse effects of price shocks on infant mortality.

The Consequences of Child Market Work on the Growth of Human Capital

World Development, March 2017 (with Daniel Suryadarma and Asep Suryahadi) Armand Sim 2

The paper measures the effect of child market work on the long-term growth of human capital, focusing on the output of the human capital production: mathematics skills, cognitive skills, pulmonary function, and educational attainment. Our full sample is drawn from a rich longitudinal dataset Indonesia Family Life Survey (IFLS). We address endogeneity of child market work using provincial legislated minimum wage as the instrument. Our instrumental variable estimation shows that child labor negatively affects mathematics skills and pulmonary function, but not cognitive skills and educational attainment. We find heterogeneities in type of work. Those who work outside of family business have lower educational attainment than those working for family business.

Working Papers

Long-run Consequences of Health Insurance Promotion When Mandates are Not Enforceable: Evidence from a Field Experiment in Ghana

Under Review

(with Patrick Asuming and Hyuncheol Bryant Kim)

We study long-run selection and treatment effects of a health insurance subsidy in Ghana, where mandates are not enforceable. We randomly provide different levels of subsidy (1/3, 2/3, and full), with follow-up surveys seven months and three years after the initial intervention. We find that a one-time subsidy promotes and sustains insurance enrollment for all treatment groups, but long-run health care service utilization increases only for the partial subsidy groups. We find evidence that selection explains this pattern: those who were enrolled due to the subsidy, especially the partial subsidy, are more ill and have greater health care utilization.

Impacts of a False-Positive Cancer Screening Result on Health Behaviors: Evidence from National Public Cancer Screening Program in South Korea

Studies linking information and health behaviors generally ask what individuals do to their health behaviors upon learning they have health problems. In this paper, I ask what individuals would do upon learning unexpectedly good news about their health after previously learning that they have health problems. This paper investigates the question by examining the effects of receiving a false-positive result from stomach cancer screening on future screening take-up rate and outpatient days. I investigate National Cancer Screening Program (NCSP) in Korea — one of the largest population-based cancer screening programs in the world — that provides cancer screening to the entire population of 40 years old and older. Using eight million observations from the universe of NCSP participants, my difference-in-differences estimate shows significant effects of a false-positive result from stomach cancer screening on its future take-up. However, I find negative effects on general health screening. The effects on outpatient days are mixed. It increased (decreased) outpatient days among men (women).
